Deadlocks

Dr. Rahul NagpalComputer Science

Outline

- System Model
- Deadlock Characterization
- Methods for Handling Deadlocks
- Deadlock Detection
- Recovery from Deadlock

System Model

PES UNIVERSITY

- System consists of resources
- Resource types $R_1, R_2, ..., R_m$ CPU cycles, memory space, I/O devices
- Each resource type R_i has W_i instances.
- Each process utilizes a resource as follows:
 - request
 - use
 - release

Deadlock Characterization

Deadlock can arise if four conditions hold simultaneously.

- Mutual exclusion: only one process at a time can use a resource
- Hold and wait: a process holding at least one resource is waiting to acquire additional resources held by other processes
- No preemption: a resource can be released only voluntarily by the process holding it, after that process has completed its task
- Circular wait: there exists a set $\{P_0, P_1, ..., P_n\}$ of waiting processes such that P_0 is waiting for a resource that is held by P_1, P_1 is waiting for a resource that is held by $P_2, ..., P_{n-1}$ is waiting for a resource that is held by P_n , and P_n is waiting for a resource that is held by P_0 .

Resource Allocation Graph

A set of vertices V and a set of edges E.

- V is partitioned into two types:
 - $P = \{P_1, P_2, ..., P_n\}$, the set consisting of all the processes in the system
 - $R = \{R_1, R_2, ..., R_m\}$, the set consisting of all resource types in the system
- request edge directed edge $P_i \rightarrow R_j$
- assignment edge directed edge $R_j \rightarrow P_i$

Resource Allocation Graph (Contd.)

Process

Resource Type with 4 instances

• P_i requests instance of R_j

• P_i is holding an instance of P_i

Resource Allocation Graph Example

 P_2

 R_4

 R_2

Graph With Cycle But No Deadlock

Basic Facts

- If graph contains no cycles ⇒ no deadlock
- If graph contains a cycle ⇒
 - if only one instance per resource type, then deadlock
 - if several instances per resource type, possibility of deadlock

Methods for Handling Deadlocks

- Ensure that the system will *never* enter a deadlock state:
 - Deadlock prevention
 - Deadlock avoidence
- Allow the system to enter a deadlock state and then recover
- Ignore the problem and pretend that deadlocks never occur in the system; used by most operating systems, including UNIX

Deadlocks Detection and Recovery

- Allow system to enter deadlock state
- Detection algorithm
- Recovery scheme

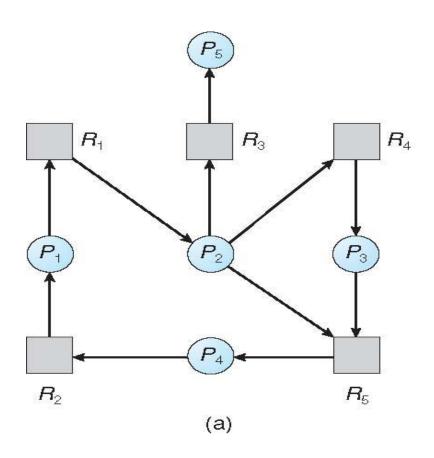

Deadlocks Detection and Recovery

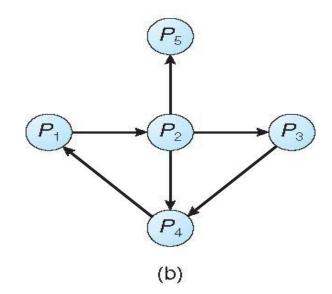

- Maintain wait-for graph
 - Nodes are processes
 - $P_i \rightarrow P_j$ if P_i is waiting for P_j
- Periodically invoke an algorithm that searches for a cycle in the graph. If there is a cycle, there exists a deadlock
- An algorithm to detect a cycle in a graph requires an order of n^2 operations, where n is the number of vertices in the graph

Deadlocks Detection and Recovery (Single Instance of Resources)

Resource-Allocation Graph

Corresponding wait-for graph

Deadlocks Detection and Recovery (Several Instance of Resources)

PES UNIVERSITY ONLINE

- Available: A vector of length *m* indicates the number of available resources of each type
- Allocation: An n x m matrix defines the number of resources of each type currently allocated to each process
- Request: An $n \times m$ matrix indicates the current request of each process. If Request[i][j] = k, then process P_i is requesting k more instances of resource type R_j .

Deadlocks Detection Algorithm

- Let Work and Finish be vectors of length m and n, respectively Initialize:
 - (a) Work = Available
 - (b) For i = 1,2, ..., n, if Allocation; ≠ 0, then
 Finish[i] = false; otherwise, Finish[i] = true
- Find an index i such that both:
 - (a) Finish[i] == false
 - (b) $Request_i \leq Work$

If no such *i* exists, go to step 4

Deadlocks Detection Algorithm (contd.)

4. If *Finish[i]* == *false*, for some i, $1 \le i \le n$, then the system is in deadlock state. Moreover, if *Finish[i]* == *false*, then P_i is deadlocked

Algorithm requires an order of $O(m \times n^2)$ operations to detect whether the system is in deadlocked state

Example

• Five processes P_0 through P_4 ; three resource types A (7 instances), B (2 instances), and C (6 instances)

• Snapshot at time T_0 :

	<u> Allocation</u>	<u>Request</u>	<u>Available</u>
	ABC	ABC	ABC
P_0	010	000	000
P_1	200	202	
P_2	303	000	
P_3	211	100	
P_4	002	002	

• Sequence $\langle P_0, P_2, P_3, P_1, P_4 \rangle$ will result in *Finish[i] = true* for all *i*

Example (contd.)

• P₂ requests an additional instance of type C

Request

ABC

 $P_0 = 0.00$

 P_1 202

 $P_2 = 0.01$

 $P_3 100$

 $P_4 002$

- State of system?
 - Can reclaim resources held by process P_0 , but insufficient resources to fulfill other processes; requests
 - Deadlock exists, consisting of processes P_1 , P_2 , P_3 , and P_4

Detection algorithm Usage

PES UNIVERSITY ONLINE

- When, and how often, to invoke depends on:
 - How often a deadlock is likely to occur?
 - How many processes will need to be rolled back?
 - one for each disjoint cycle
- If detection algorithm is invoked arbitrarily, there may be many cycles in the resource graph and so we would not be able to tell which of the many deadlocked processes "caused" the deadlock.

Recovery from Deadlock – Process Termination

PES UNIVERSITY ONLINE

- Abort all deadlocked processes
- Abort one process at a time until the deadlock cycle is eliminated
- In which order should we choose to abort?
 - 1. Priority of the process
 - 2. How long process has computed, and how much longer to completion
 - 3. Resources the process has used
 - 4. Resources process needs to complete
 - 5. How many processes will need to be terminated
 - 6. Is process interactive or batch?
